Abstract

The electrochemical deposition of a nickel–iron alloy from a plating solution based on a deep eutectic solvent (a eutectic mixture of ethylene glycol and choline chloride) in the presence of water additives (up to 15 wt.%) has been investigated. It is shown that the codeposition of Ni and Fe is accompanied by an acceleration of the discharge of iron(II) ions (a more electronegative component). A “normal” codeposition behavior is observed in a solution without extra water, whereas an “anomalous” codeposition occurs in a deep eutectic solvent with added water (preferential deposition of iron as a less noble component). The addition of ascorbic acid to the plating solution based on a deep eutectic solvent not only prevents the oxidation of iron(II) ions by atmospheric oxygen but also inhibits the partial reaction of nickel electrodeposition. The iron content in the coating increases both with an increase in the contents of Fe(II) ions and water in the plating bath and with an increase in the cathodic current density. The deep eutectic solvent-based solution allows fabricating uniform nanocrystalline deposits of a nickel–iron alloy with an iron content of up to 10–15 wt.%. The electrocatalytic properties of Ni, Fe, and Ni–Fe coatings are evaluated with respect to the hydrogen evolution reaction in an alkaline medium. It is shown that even at a low iron content in the alloy (~ 2–7 wt.%), a significant increase in electrocatalytic activity is observed (an increase in the exchange current density).

Introduction

Nickel-based alloys are one of the most common types of electroplated coatings, since they provide high corrosion and wear resistances, enhanced microhardness, valuable protective, magnetic, decorative, and electrocatalytic properties [1]. The physicochemical and service properties of nickel-based electrodeposited coatings can be significantly improved by alloying with various metals, i.e., via alloy formation. Nickel–iron alloy is one of the most attractive materials in this respect. Codeposition of iron with nickel is performed to reduce the cost of production, prepare soft magnetic materials, and provide special optical properties,

good electrical conductivity, and satisfactory corrosion resistance [2]. In addition, nickel–iron alloys, including electrodeposited coatings, attract attention as electrocatalysts in the process of water electrolysis [3–10], which is extremely important in the context of the development of inexpensive and highly efficient electrode materials for green hydrogen energy [11–15]. Significant advantages of the nickel–iron alloy in comparison with other potentially attractive electrocatalytic materials are its bifunctionality (i.e., the possibility of using both for cathodic hydrogen evolution and for anodic oxygen evolution) and the use of inexpensive earth abundant elements.

Commonly, the electrochemical deposition of nickel–iron alloys is performed in aqueous plating solutions [2, 5, 6, 16–25]. Aqueous plating baths are readily available, cheap, and well researched. However, the possibilities for their further improvement have been largely exhausted, and therefore, in recent decades, the issue of the development of new types of solutions as promising alternatives to traditional water systems for the deposition of metals has been put on
