PHYLOGENETIC SYSTEMATICS

Objectives

1. To become familiar with the cladistic approach to reconstruction of phylogenies.
2. To construct a character matrix and phylogeny for a group of very unusual organisms.
3. To interpret the evolutionary history of traits based on a phylogenetic reconstruction.

PART I. INTRODUCTION

The branch of biology known as **systematics** expressly deals with the evolutionary history or **phylogeny** of groups of organisms. Systematists seek to produce a classification or **taxonomy**, which reflects the evolutionary history of a particular group of organisms. For instance, two species that are classified in the same genus are considered to be more closely related (i.e., share a more recent common ancestor) than species in different genera within the same family. Such a system is said to be hierarchical.

The following hierarchy of classification is used in biology:

Kingdom/Domain
Division or Phylum
Class
Order
Family
Genus
Species

How can systematists be sure their taxonomic classification reflects the true evolutionary pathway? We can't go back in a time machine to tell when various groups evolved. Instead, most systematists use general morphology to draw conclusions about ancestry. For instance, a leopard frog and a milk frog appear to be more similar to each other than either is to a toad. This observation is reflected in the fact that the two frogs are classified in the genus *Rana* and the toad in the genus *Bufo*.

Unfortunately, measures of morphology can be subjective. Two systematists looking at the same organisms may make different judgements about the relative similarity of those organisms. In the past 25 years, a technique has been developed which provides a more objective way of assessing evolutionary relationships. The technique, called **cladistics**, was developed by the German biologist, Willi Hennig. Cladistics has transformed the way that systematic research is conducted.

In short, cladistics is a method to reconstruct the probable evolutionary pathway of a group of organisms. The technique is designed to identify **clades**, groups of organisms that all share a common ancestor. Clades are usually depicted as branching diagrams called **cladograms** or evolutionary trees. Let's consider the simple cladogram below. Time is measured vertically in a cladogram. This cladogram tells us that the first event was the evolutionary split into two different lines, one leading to species A and one to the other branch of the tree. The next event was the splitting of B from the line that leads to C and D. The final and most recent event is the splitting of C and D into two separate species.

You can distinguish three different clades in this cladogram: one clade that includes A, B, C & D because they all share a common ancestor, a second smaller clade that includes only B, C & D because they are on a separate branch of the cladogram from A, and an even smaller clade including only C & D. A taxonomist might use this information to place C and D in the same genus, B in a different genus but in the same family as C & D, and finally A in a different family but in the same order as B, C and D.
