## Energy and Cellular Respiration

Energy is the ability to do work. In biology, energy is often measured in kilocalories (kcal) or kilojoules (kJ). Cellular respiration is the process by which cells convert the chemical energy stored in glucose into a form that can be used to power cellular processes. This process occurs in the mitochondria of eukaryotic cells and in the cytoplasm of prokaryotic cells. The overall equation for cellular respiration is:

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O + \text{Energy}$$

The energy released during cellular respiration is used to drive various cellular processes, such as the synthesis of macromolecules, the transport of ions, and the contraction of muscles. The energy is stored in the form of adenosine triphosphate (ATP), which is the primary energy currency of the cell. ATP is synthesized from adenosine diphosphate (ADP) and inorganic phosphate (Pi) using the energy released during cellular respiration.

Cellular respiration is a multi-step process that involves the breakdown of glucose into carbon dioxide and water. The process is divided into three main stages: glycolysis, the citric acid cycle, and oxidative phosphorylation. Glycolysis is the first stage and occurs in the cytoplasm. It involves the breakdown of glucose into pyruvate, which then enters the mitochondria. The citric acid cycle is the second stage and occurs in the mitochondrial matrix. It involves the breakdown of pyruvate into carbon dioxide and the release of electrons. Oxidative phosphorylation is the third stage and occurs in the inner mitochondrial membrane. It involves the use of electrons to drive the synthesis of ATP from ADP and Pi. The overall process of cellular respiration is highly efficient, with up to 40% of the energy stored in glucose being converted into ATP.
