**Abstract** – This paper provides a design approach and thermodynamic analysis of an solar stirling model. Out of the three Configurations viz. Alpha,Beta and Gamma an Alpha configuration was Chosen because of its ease of fabrication. Parabolic solar concentrator is used to provide Heat to the Engine. The main objective was to determine how much work can be extracted from a 49cc Stirling Engine. Further the Effect of regenerator effectiveness on Stirling cycle efficiency, Variation of expansion volume, Compression volume and total volume is also calculated with respect to crank angle variation.

**Key Words:** Solar Stirling model, Alpha Configuration, Stirling Engine, Parabolic Solar Concentrator, regenerator effectiveness, crank angle, expansion volume, compression volume.

### 1. INTRODUCTION

Stirling engine is a mechanical device working theoretically on the Stirling cycle, in which compressible fluids, such as air, hydrogen, helium, nitrogen or even vapors, are used as working fluids. The Stirling engine offers possibility for having high efficiency engine with less exhaust emissions in comparison with the internal combustion engine. The earlier Stirling engines were huge and inefficient. However, over a period of time, a number of new Stirling engine models have been developed to improve the deficiencies.

The modern Stirling engine is more efficient than the early engines and can use any high temperature heat source. The Stirling engine is an external combustion engine. Therefore, most sources of heat can power it, including combustion of any combustible material, field waste, rice husk or the like, biomass methane and solar energy. In principle, the Stirling engine is simple in design and construction, and can be operated easily.

Direct solar-powered Stirling engines may be of great interest to countries where solar energy is available in unlimited quantity. To use direct solar energy, a solar concentrator and absorber must be integrated with the engine system.

### 1.1 Configuration of Stirling Engine

There are mainly three configurations of stirling engine namely, Alpha, Beta and Gamma.

- In the alpha-configuration a displacer is not used. Two pistons, called the hot and cold pistons, are used on either side of the heater, regenerator, and cooler. These pistons move uniformly in the same direction to provide constant-volume heating or cooling processes of the working fluid. When all the working fluid has been transferred into one cylinder, one piston will be fixed and the other piston moves to expand or compress the working fluid. The expansion work is done by the hot piston while the compression work is done by the cold piston.
- In the beta-configuration, a displacer and a power piston are incorporated in the same cylinder. The displacer moves working fluid between the hot space and the cold space of the cylinder through the heater, regenerator, and cooler. The power piston, located at the cold space of the cylinder, compresses the working fluid when the working fluid is in the cold space and expands the working fluid when the working fluid is moved into the hot space.
- The gamma-configuration uses separated cylinders for the displacer and the power pistons, with the power cylinder connected to the displacer cylinder. The displacer moves working fluid between the hot space and the cold space of the displacer cylinder through the heater, regenerator, and cooler. In this configuration, the power piston both compresses and expands the working fluid. The gamma-configuration with double-acting piston arrangement has theoretically the highest possible mechanical efficiency. This configuration also shows good self-pressurization.

Addressing the challenge of climate change requires the large scale development of significant renewable energy generation but also requires these intermittent energy sources to be balanced by energy storage or demand management to maintain a reliable electric grid In addition a centralized generation paradigm fails to capture and utilize thermal energy for combined heat and power abandoning a large portion of the available value from the primary energy source A solar thermal electric system utilizing Stirling engines for energy conversion solves both of these shortcomings and has the potential to be a key technology for renewable energy generation The ability to store thermal energy cheaply and easily allows the reliable generation of output power even during absences of solar input and operating as distributed generation allows the output thermal stream to be captured for local heating applications Such a system also can achieve relatively high conversion efficiencies is fabricated using common and benign materials and can utilize alternate sources of primary energy in an extended absence of solar input This dissertation discusses the design fabrication and testing of a Stirling engine as the key component in a solar thermal electric system In particular the design addresses the low temperature differential that is attainable with distributed solar with low concentration ratios and is designed for low cost to be competitive in the energy space The dissertation covers design fabrication and testing of a 2.5 kW Stirling Engine with a predicted thermal to mechanical efficiency of 20% representing 60% of Carnot efficiency operating between 180 C and 30 C The design process and choices of the core components of the engine are discussed in detail including heat exchangers regenerator pistons and motor alternator and the process for modeling simulation and optimization in designing the engine Finally the dissertation covers the assembly and experimental testing that validates the design in terms of heat exchanger performance losses kinematics and cycle work
